~~OFFICIAL USE ONLY~~

MARINE LANDING AND BEACHING INFORMATION FOR ALL SITES ENIWETOK ATOLL

ALICE — LCMs and LCUs beach on sand bar through break in reef. Require plus 1.5 tide or under. Tracked equipment and vehicles only.

Channel Markings: None at present.

CLARA — LCMs beach on sand bar through break in reef. Require plus 1.5 tide or under. Tracked equipment and vehicles only.

Channel Markings: None at present.

GENE
HELEN
IRENE — Causeway out between HELEN and GENE. Landings for LCUs and LCMs on west side of GENE. LCMs can beach at IRENE but require a plus 2.5 tide. IRENE and HELEN connected by causeway. Old channel at GENE useable but not recommended.

Channel Markings: None.

JANET — LCMs and LCUs at any tide.

Facilities: Hard sand ramp. (Note: Freight pier in damaged condition, not recommended for use until repairs made.)

Channel Markings: None.

KATE — LCMs requirea plus 1.5 tide and LCUs require a plus 3.0 tide.

Facilities: Sandy beach landing.

Channel Markings: None.

LUCY — LCMs require a plus 1.5 tide and LCUs require a plus 3.0 tide.

Facilities: Sandy beach landing.

Channel Markings: None

~~OFFICIAL USE ONLY~~

MARINE LANDING AND BEACHING INFORMATION FOR ALL SITES (Cont'd)

MARY

LCMs can enter at any tide. LCUs require a plus 2.0 tide.

Facilities: Sandy beach landing.

Channel Markings: None.

NANCY
OLIVE
PEARL

LCU (Only) require a plus 2.0 tide.

Facilities: Sandy and coral beach landing.

Channel Markings: None.

RUBY
SALLY
TILDA
URSULA

Connected by causeway. Entrance channel at URSULA. LCMs and LCUs can enter at any tide.

Facilities: Freight pier and concrete ramp.

Channel Markings: One lighted entrance buoy (Fl.-W.) and eleven channel buoys. (Oil drums; 6 red and 5 black.)

Note: The channel to the causeway landing between TILDA and URSULA and the channel to the damaged pier at SALLY have sanded in and are not being used. (Some old channel marking buoys are still in place.)

WILMA

LCMs can enter at any tide. LCUs require a plus 2.0 tide.

Facilities: Sandy beach landing.

Channel Markings: None.

YVONNE

LCMs, LCUs, and YTLs (Tugs) can enter at any tide.

Facilities: Freight pier and [illegible] concrete ramp.

Channel Markings: One lighted entrance buoy (Fl. W.).

~~OFFICIAL USE ONLY~~

~~OFFICIAL USE ONLY~~

MARINE LANDING AND BEACHING INFORMATION FOR ALL SITES (Cont'd)

ZONA — DUKWs only.

ALVIN
BRUCE
CLYDE

LCMs can enter at any tide. LCUs require a plus 2.0 tide.

Facilities: Sandy beach landing.

Channel Markings: None.

DAVID

LCMs, LCUs, and YTLs (Tugs) can enter at any tide.

Facilities: Freight pier and a sandy beach landing.

Channel Markings: None.

ELMER

LCMs, LCUs, and YTLs (Tugs) can enter at any tide.

Facilities: Freight pier, personnel pier and two concrete ramps.

Channel Markings: None.

FRED

LCMs, LCUs, and YTLs (Tugs) can enter at any tide.

Facilities: Freight pier, personnel pier, 40 feet concrete ramp by personnel pier and sand ramp by freight pier.

Channel Markings: One clearance buoy just off the personnel pier.

GLORY
HENRY
IRVIN
JAMES
KENT

LCMs (Only) require a plus 2.0 tide.

Facilities: Pure coral beach landing. (Sandy in spots.)

Channel Markings: None. (Note: Not used very much.)

~~OFFICIAL USE ONLY~~

~~OFFICIAL USE ONLY~~

MARINE BEACHING AND LANDING INFORMATION FOR ALL SITES (Cont'd)

LIMOY

LCMs require a plus 2.0 tide and LCUs require a plus 4.0 tide.

Facilities: Sandy beach landing

Channel Markings: One large nun buoy (Red #2) and four other channel buoys (oil drums) (3 red and 1 black).

Note: Red nun buoy #2 serves also as a mooring buoy for LCMs. Keep all red buoy close to starboard when entering channel. Beaching area is between the last red buoy (#8) and only black buoy (#7).

OSCAR

LCMs (Only) at any tide.

Facilities: A ladder is at the southeast side of tower.

Channel Markings: None.

MACK

LCMs and LCUs at any tide.

Facilities: Landing platform is at the north side of tower base.

Channel Markings: None.

ENGINEERING CALCULATION SHEET

HOLMES & NARVER, INC.
ENGINEERS - CONSTRUCTORS

JOB NO. 942
SHEET 1 OF
BY ES DATE

TITLE HEIGHT OF TIDE AT ANY TIME

Obtain from the predictions the high water and low water, one of which is before and the other after the time for which the height is required. The difference between the times of occurrence of these tides is the duration of rise or fall, and the difference between their heights is the range of tide. Find the difference between the time of the nearest high or low and the time for which the height is required. (Cont'd at bottom of page)

Enter the table with the duration of rise or fall, which most nearly agrees with the actual value, and on that horizontal line find the time from the nearest high or low water which agrees most nearly with the corresponding actual diff. The correction sought is in the

TIDE TABLES

ENIWETOK ATOLL, MARSHALL ISLANDS

1957

This tabulation is extracted from "Tide Tables, Central and Western Pacific Ocean and Indian Ocean, 1957", and published by the U.S. Department of Commerce, Coast and Geodetic Survey.

Datum, elevation 0.0, is defined in the above publication as follows: "Heights are reckoned from the datum of soundings on the largest scale charts of the locality which is ½ foot below mean low water springs" for Kwajalein Atoll, Marshall Islands.

The reference station is Kwajalein Atoll, time meridian 180 degrees east. The following tabulation appears in Table 2. - Tidal Differences and ranges:

	Lat	Long.	Time	Ranges	
				Mean	Spring
Eniwetok Atoll	11° 21'	162° 21'	-05 min.	2.7'	3.9'

Range is the difference between successive tides, i.e., between a high and a low or a low and a high. Mean range is the average range of all tides in the year. Spring range is the average of the largest ranges in the year. Springs occur once each lunar month (approximately 28 days) when the highest highs and the lowest lows are recorded.

The values in this tabulation are based on average weather conditions. Unusual weather, particularly high winds from a direction other than seasonally normal, affect both the times and the heights.

Each site in the Atoll has a slightly different time and height of highs and lows. This can be disregarded for all practical purposes in the lagoon. The water level on the ocean reef is always higher than that of the lagoon, the difference varying from a few tenths to 1.5'.

BUILDING & STRUCTURE NUMBERS

HOLMES & NARVER, INC.

REVISED TO 1 OCT. 1956

MISC. 415

NOTE: Any corrections or changes to this list should be made only on the master list which is maintained in the Office Engineering & Design Department of the Engineering Division

54

GENERAL NOTES

1. For further information on sizes and types of buildings, refer to the As-Built Drawings.

*2. Column denoted by an asterisk contains numbers which represent General Layout Drawing Number or area on which building appears on the new 1" - 50' topographic sheets.

3. The building numbers in this index pertain to Holmes & Narver Plans, General Layouts and Survey notes.

4. Symbol beside building number (M) indicates Military owned building or structure.

5. Symbol beside building number (C) indicates A.E.C. owned building or structure that is capitalized, or, Construction-Work-Is-In-Progress.

BUILDING & STRUCTURE NUMBERS

HOLMES & NARVER, INC.

REVISED TO 1 OCT 1956

MISC. 416

NOTE: Any corrections or changes to this list should be made only on the master list which is maintained in the Office Engineering & Design Department of the Engineering Division.

GENERAL NOTES

1. For further information on [illegible] of buildings, refer to the As-Built [illegible].

*2. Column denoted by an asterisk contains numbers which represent General Layout Drawing Number or area on which building appears on the new 1" = 50' topographic sheets.

3. The building numbers in this index [illegible] Delong & Harper Plans, General Layout and Survey [illegible].

4. Symbol beside building number (M) [illegible] facilities owned building or structure.

5. Symbol beside building (C) indicates [illegible] owned building or structure that is capitalized, (i.e. [illegible]-Work-In-In-Progress.

TIDE TABLE

BIKINI Atoll, MARSHALL Islands

1957

This [illegible] is [illegible] from [illegible] Bureau, Central and Western Pacific Ocean, and Tarawa Canton, Fanning, and [illegible] Charts by the U.S. Department of Commerce, Coast and Geodetic Survey.

Data, [illegible] is obtained by the [illegible] addition or [illegible] "Heights are reckoned from the datum of soundings on the [illegible] charts of the locality under [illegible] reduction to "low water datum" for Bikini Atoll, Marshall Islands.

The meters are counted in Bikini Atoll, [illegible] 180 degrees east. The following [illegible] phases in [illegible] time differences and ranges:

	Time		Range	
	High	Low	High	Low
Bikini Atoll	[illegible]	[illegible]	[illegible]	[illegible]

Range is the difference between successive [illegible], i.e., between a high and a low or a low and a high. Mean range is the average range of all tides in the year. Spring range is the average range occurring twice a month, Spring tides are [illegible] (opposite to the sun) when the [illegible] and the moon are [illegible].

The values in this [illegible] are based on average weather conditions. Unusual weather, particularly high winds [illegible] can cause [illegible] normal, affect both the [illegible] and the heights.

Each side of the chart has a graphic [illegible] and heights of high and low. This can be interpolated for the [illegible] printed in the [illegible]. The water level on the [illegible] is [illegible] than that of the [illegible], the difference varying from [illegible] to [illegible].

Specifications and Procedure

The basis of classification of geodetic control surveys is the accuracy with which the length and direction of a line can be determined. Since it is impossible to ascertain the absolute error, it is essential that the procedure in executing the survey conform to standards which have been established as the result of extensive experimentation and research. For this purpose, the triangulation survey of this department [illegible] Coast and Geodetic Survey.

Specifications are to be followed for each class of the work and much other information of value is contained in Special Publication No. 247, Manual of Geodetic Triangulation published by the USC&GS. This manual will be the textbook for precise surveys, and persons involved in the [illegible] should familiarize themselves with the contents. The following is a summary of the procedure involved in making a survey, and is not intended to replace [illegible] to the manual.

Generally, the [illegible] accuracy and the points whose interrelation are required will be specified by the Client. The approximate locations of the triangulation stations will be determined based on reconnaissance and conformance to strength of figure requirements. Instructions including the above information will be issued to the field for execution of the [illegible].

Reconnaissance. Before observing can be initiated, the stations must be physically established and, if necessary, observing towers erected. Intervisibility of stations must be determined, and the location and height of towers so established that the line of sight has a minimum vertical clearance of ten feet from any object. The minimum safe clearance both vertical and horizontal is dependent on atmospheric conditions, and reference to [illegible] 12", Manual of Reconnaissance for Triangulation, is recommended for information on the subject. Formulas and a table for determining intervisibility will be found in [illegible], page [illegible]. The computed heights of towers to compensate for the earth's curvature [illegible] than the ten feet will give the actual height of towers.

Reference. The following reference [illegible] published by the U.S. Coast and Geodetic Survey should be available at [illegible] where precise triangulation is to be accomplished. The chapters on triangulation [illegible] in many textbooks are based on information from these manuals.

[illegible] 247, Manual of Geodetic Triangulation
[illegible] 245, Manual of Reconnaissance
[illegible] 249, Manual of First Order Triangulation
[illegible] 245, Manual of Second Order Triangulation
[illegible] 248, Manual of Astronomical Triangulation
[illegible] 5, Formulas and Tables for the Computation of Geodetic Positions

[illegible] 247 and 249 are superseded by [illegible], but do contain more detail on some subjects.

INSTRUCTIONS FOR USE OF THE [illegible] THEODOLITE

(Issued by the U.S. Coast and Geodetic Survey)

These instructions are intended for the Wild T-2 Theodolite, but contain information applicable to the Wild T-3.

1. Unpacking and setting up of the instrument. The case is set up with the felt to the rear, and the two lateral screws of the base plate are unscrewed. The hood is then carefully lifted and the two clamping levers are unloosed. The base plate which is fastened to the tripod with a milled screw, is taken out and set on the stand, centered, the three levers are pulled out, the theodolite is set in and the tribrach screws are locked fast with the clamping levers.

2. Leveling. The centering is not altered anymore by leveling, since the point of support of the plumb bob is the plane which passes through the tips of the tribrach screws.

The theodolite should be turned several times about the vertical axis and the telescope transmitted before starting to level.

3. Focussing. The focussing of the eye piece is done by turning the black milled ring until the crosswires become very sharp and black, while the telescope is pointed on a moderately bright background. A person should observe and remember the setting of the ring on the numbered scale, and then use this for future focussing. To focus on the image of the sighting point, turn the nickel focussing ring (testing for freedom of parallax between image and crosswires, by movement of the eyes). For the focussing of the reading microscope, the milled black ocular tube, at the side of the telescope, is turned until the graduations of the circle become sharply defined.

By changing eye-pieces, a person may obtain magnifications of 24, 30 or 40; normally, the magnification of 30 should be used, and this eye-piece should also be used for the zenith prism.

4. Reading the circle. The horizontal and vertical circles are read in the microscope, adjoining the telescope. On the right, next to the slow motion screw for the vertical circle is the milled head screw for the inverting contrivance. By turning the screw clockwise until it stops, the horizontal circle becomes visible in the microscope; then by turning it counterclockwise the image of the vertical circle becomes visible.

The illumination of the circles should be as bright and as equally illuminated as possible. To do this, the illuminating prisms are turned. During the measurement of an angle, the illumination should not be changed. In the reading microscope appear the images of the diametrically opposite portions of the circle, separated by a fine horizontal line, and below (or to the side) the scale images of the second drum.

5. Horizontal Circle Readings. The horizontal circle is graduated to 4 minutes, and is read (left to right) by means of the index, to 2 minutes. The lower row of degree figures is read.

To this circle reading is added double the reading of the seconds drum, since the drum is half [illegible]. The drum is numbered by tenths from 0.0 to 60.0, but this represents an angle of 2' on the face, so that single drum reading is only half the true value and must be multiplied by two before being added to the circle reading. In practice two readings of the drum should be taken and the sum of the two used to the circle reading, thus accomplishing the same result as multiplying the drum reading by 4 and giving the added accuracy of two micrometer readings instead of one. The following example will make this clear:

Circle reading		Seconds drum			Total Reading		
°	'	1st read.	2nd read.	sum	°	'	"
104	58	6.8	6.9	13.7	104	58	13.7
119	10	11.0	11.0	22.0	119	11	22.1
140	20	19.8	20.0	39.8	140	20	39.8
158	30	33.2	32.9	66.1	158	31	06.3
172	52	7.0	7.0	14.0	172	52	14.0
0	12	17.9	17.8	35.7	0	13	35.7
43	28	9.0	9.1	18.1	43	29	18.1

Since only two micrometer readings are required instead of six as in 3-micrometer instruments, greater care and greater refinement of drum readings must be taken with the two readings that are considered sufficient with 3-micrometer theodolites.

The seconds drum reads directly to 0.1 double seconds (0.2 seconds) and all readings should be taken to this degree of refinement. Record the sum of the two readings, also the [illegible] and seconds readings and the direction to the nearest tenth of seconds.

Experience shows that the difference between careful micrometer readings will seldom be greater than 0.3 double seconds (0.6 seconds) and generally no more than 0.1 double seconds (0.2 seconds). If the two readings vary by more than 0.3 double seconds, (0.6 seconds), they should be repeated until two concordant readings are obtained.

6. Vertical circle readings. Before taking readings of the vertical angle, [illegible] the vertical circle bubble as described in the section on the single micrometer instrument and [illegible] the vertical circle bubble before reading the circle. The following is an example of the readings:

Direct	[illegible]	[illegible]
Reverse	[illegible]	[illegible]
Difference (angle of depression)	[illegible]	

With vertical circle [illegible]

Vertical circle readings [illegible] indicate angles of elevation. depression

With vertical circle right

Vertical circle readings [illegible] indicate angles of elevation depression

Records. Forms are provided for each operation in recording the results of observing and computing. These records should be kept on transparencies in order that reproductions can be made of all records of the survey.

All computations which are required to complete these forms should be included in the records of the survey. They should be recorded in an orderly manner, and in sufficient detail that the computations can be checked at the Home Office. References should be made to field books, map compilation data used in computing the survey.

7. Electrical Illumination. There are two sources of illumination:

(a) That for the horizontal circle,
(b) That for the vertical circle and cross-wires.

The record drum is illuminated by the light for whichever circle is being read. The horizontal circle lamp is the one closest to the three wires attached to it: The vertical circle lamp is the one closest to the white. Remove the horizontal and one vertical lamp and insert in prism tube. Then in the clips in the base plate of the instrument case before using the electrical illumination devices.

The cross wires are illuminated by a prism in the upper inside the telescope which intercepts part of the light which goes to the vertical circle. This prism has no adjustment.

A rheostat may be installed in the circuit to regulate the cross-wire illumination. Tests should be made to see if it should be installed between the battery and horizontal circle lamp or between the horizontal and vertical circle lamps. When the current is adjusted to the proper value, a permanent rheostat can be attached if necessary.

To switch off the circuit, pull out one of the small pins at the end of one of the wires of the horizontal circle illuminating attachment.

A very important point is the illumination of the horizontal circle. A diffused light is essential, and this diffusion is not provided by the frosted bulbs, provided with the instrument, to the desirable degree. Bulbs should be painted white, or a piece of paper should be placed over the end of the lamp tube for the illumination of the horizontal circle to give the required diffusion. Permanent changes will be made when the engineers have given the problem their attention. In the meantime, a tube of white paint and a bottle of shellac should be carried by field parties painting bulbs.

Flashlight bulbs for cross-hair illumination of either 2.5 or 3.8 volts may be used. The latter will likely be found more reliable for illumination current from the batteries supplied in a case with some of the instruments. Some bulbs apparently have the wrong screw thread and size of bulb for the prism tube. Before leaving for the field select proper spare bulbs for emergency.

8. Other Points. Watch out for dirt in the horizontal circle. Every few nights close the circle to zero positions by closing on the index at the end of the half set.

Carry the theodolite upright when in the car; do not let this case rest on its side. The theodolite is fastened to the case by the bottom only, and if it rests on its side any vibration will be added to the upper part of the vertical axis, an undesirable condition.

Laboratory tests indicate that the accuracy of determination drops considerably when the telescope is not exactly focused. It is therefore desirable to exactly focus the telescope on a star, after the proper focus is determined for always use the telescope at that focus for precise work. After the exact focus is obtained put a scratch across the edge of the focusing ring and the adjacent part of the telescope tube, so that exact focus may be established or checked at any time.

9. Description of the table.

Effective aperture of the eyepiece objective (free [illegible] 3/8 inches)
Magnification (3 eyepieces) [illegible] 23.4 and 38.5
Length of telescope [illegible] mm. (10 inches)
Sensitivity of plate levers, approx. 2 [illegible] per division
Sensitivity of vertical circle level, approx. [illegible] per 2 mm.
(The coincidence adjustment of the bubble [illegible] doubles the accuracy of centering.)
Magnification of reading microscope [illegible]
Diameter of horizontal circle [illegible] mm. (5½ inches)
Diameter of vertical circle [illegible] mm. (5 3/4 inches)
Division of horizontal circle [illegible]
Division of vertical circle (1/2 double [illegible] minutes, (really 8 minutes)
Value of smallest division of seconds drum, approx. (.1 seconds, really 0.2 seconds
Vertical circle bubble adjusted so that it [illegible] of the horizontal wire.

Weight of instrument [illegible] 11.5 kg. (25.3 lbs.)
" " case [illegible] 5.9 kg. (12.9 lbs.)
" " tripod and accessories [illegible] 7.5 kg. (16.5 lbs.)
Resolving power (24X eyepiece) 2"
" " (30X ") 2"
" " (40X ") 3"

10. Zenith prism. This prism is to be used for astronomic observations. The Zenith prism is a feature of the new [illegible]. The 30 magnification eyepiece is to be used for it.

11. Packing the instrument. The levers of the base plate are released, the instrument is lifted out and set on the base plate of the packing box. In front on one of the supports of the tribrach screws is a nickel mark. A similar mark is on the front edge of the base plate, the instrument must be so set in, that these two marks correspond, then the clamps are closed. The telescope is turned over until the eyepiece almost touches the standards, the standards are turned in the horizontal direction a way that the eyepiece comes over the two marks. The clamping screws for the vertical circle and the horizontal circle are moderately tightened. The base plate with the levers pushed in is again attached to the standards or it may be left on the stand. After carefully closing the hood, the two screws for tightening the hood are turned [illegible].

NOTE: Paragraphs 1 and 11 do not apply to the type of instrument now furnished with the T-3 theodolite owned by this organization.

Specifications of the USC&GS require a set of sixteen positions to be observed for first order triangulation, and six to twelve for second order. Recommendations of the local office of this organization are that for average conditions eight positions be observed for second order triangulation.

The initial settings of the circle for the eight and sixteen position sets are as follows. It is not necessary to set the circle closer than about one-half minute to the setting given.

8 Position

(1)	D	0°	00'	10"
(2)	R	269	00	25
(3)	D	45	00	35
(4)	R	314	00	50
(5)	D	90	00	10
(6)	R	269	00	25
(7)	D	135	00	35
(8)	R	359	00	50

16 Position

(1)	D	0°	00'	10"	(9)	D	90°	00'	10"
(2)	R	179	00	25	(10)	R	269	00	25
(3)	D	22	30	35	(11)	D	112	30	35
(4)	R	202	30	50	(12)	R	292	30	50
(5)	D	45	00	10	(13)	D	135	00	10
(6)	R	224	00	25	(14)	R	314	00	25
(7)	D	67	30	35	(15)	D	157	30	35
(8)	R	247	30	50	(16)	R	337	30	50

After completion of the direct readings on the initial light, direct pointings and readings are made to the clockwise or next additional light of the schedule. Then the telescope is plunged and pointings and readings made on the lights in the reverse order to and including the initial light. This completes position number one. With the telescope remaining reversed, the circle is set for position two, and pointings on the initial and other lights are made in the same manner as for position one. This procedure is repeated until the required number of positions have been observed. The reflected pointings are not observed.

It frequently happens that one or more lights are not visible during all or part of the time that the main sights are being taken upon the other stations. Little time should be spent waiting for a light to rise. The position missed can be observed later, using the same initial light as for the first series, or some other main scheme station observed most during the series.

Every effort should be made to complete satisfactory sets to all required stations while occupying a station, as a second occupation will generally need another night's work if the preceding station is included.

Rejection of Observations

The greater part of the time involved in the observing program is in preparation to observe, transporting, setting up, adjusting lights, etc. Once ready to go, any refinement in observing which may help to decrease the probability of re-observing a station is well justified. A rigorous application of the rejection limits to observations, even though the occasional rejected one just outside the limit, will result in a saving of time and effort.

The following is a summary of rejection rules as applied by the USC & GS, and may be found in more detail in C&GS Spec. Pub. 247, pages 170 and 171.

(1) Any measurement of a direction deviating by more than four seconds from the mean for first-order triangulation, and by more than five seconds for second order, shall be rejected if it was observed using the same position setting.

(2) In applying the rejection limit the value of a direction should be rounded off to the nearest tenth of a second, and the criterion applied to each observation to the tenth of a second.

(3) If any observations are so far from the approximate mean as to obviously exceed the limit, these should be rejected before taking the trial mean and thus possibly re-observed.

(4) No reading should be rejected if it falls within the limit of retention unless rejected at the time of observation.

(5) A trial mean is taken, and using the rejection limit any observation (including the individual ones forming a position mean) which differs by more than the limit from the trial mean is rejected. The rejected positions are re-observed.

(6) After a trial mean is obtained using the rejection limit applied, none of the observations rejected should be again included even though the new mean would bring them within the limit of rejection.

(7) Using a new mean, the rejection limit is again applied. If any of these observations fall outside the rejection limit they are rejected, and new observations and new means taken until all accepted positions are within the limits of the rejection.

(8) If one reading of two or more observations falls without and one within the limits of rejection, do not use the mean even though it comes within the limit. Use judgment with the reading within the limit and reject the other.

(9) If two readings fall without the limits, one being abnormally high and the other abnormally low, and the mean falls within the limit, both readings should be rejected.

(10) If two or more readings have been taken for a single position, the mean should be used if the readings are within the limit of retention.

(11) Occasionally conditions will be encountered which make it difficult to bring all readings within rejection limits. There will be an abnormal spread in direct and reverse readings, but the position mean will be well within the limits. If the number of rejections is averaging much in excess of ten percent of the entire number of observations, the rejection limit may be increased. Before this is done, every effort should be made to determine the cause of the large range.

Record of Topographic Directions

The following Record of Topographic Directions contains the field record of observing an eight-position set to record by [illegible] directions. It is followed by an "Abstract of Directions" which contains the position directions and the mean of the eight positions in each direction.

The process of establishing the mean direction of a position may be understood by a study of the records for position No. 1 only.

(a) The direct and reverse readings are recorded for each observed station.

(b) The initial and ending readings on the initial station are meaned.

(c) The mean reading on the initial station established by a and b is subtracted from the mean D and R for each successive observed station to establish the direction for that position.

A trial mean is established by dividing the sum of the directions for each of the eight positions by the number of positions. In this case (see Abstract of Directions) 40.0" for station Baker and 00.0" for station Log.

With these trial means each position is checked for compliance with rejection limits. Two examples of rejection follow:

Position No. 4. The trial mean for direction Baker is 40.0". It is obvious that 46.5 is outside the five second rejection limit.

The mean D/R for a direction of 40.0 is obtained by subtracting the difference between the direction and zero D/R for Baker at this position, or: 47.5 - (46.5 - 39.0) = 39.5.

It is then found that the direct reading 39.5 is within limits and that the reverse reading 39.5 is outside the limits and is rejected. 21.5 is accepted for the mean D/R.

Position No. 2. The reading 00.0, or 60.0, is obviously outside the five-second rejection limit of 40.0 + (46.0 - 45.0) + 50.0. The direct and reverse readings of 54.0" and 56.0" are both outside the limits so the position is rejected and is recorded (see below of the same page).

In the Abstract of Directions a line is drawn through the original direction for Position 4 of 46.5" and the new direction of 39.5" is entered. The new direction for Position 7 of 39.0" is entered in the same manner.

A new mean direction is established and a check is made of the positions to determine that the directions for the positions and all position mean D's & R's are within the limits of their means.

It will be found that the process can be applied with equal ease to the successive portions of channels, and that the readings which are obtainable outside limits. This possible re-observing there confirms the determination of total mean, and will enable the number of observations to be reduced. For instance, for the directions of 60°, 90° and 120° it was assumed that the third observation on Baker, when a direction of 75° 1' was determined for horizon A, would be sufficient as indicated.

Triangle Closure. A good example for triangle closures are that the maximum error in closure of any triangle shall not exceed three seconds for first order, five for second, and ten for third order, but that the average triangle closure where triangulation is being executed in a network or figures shall not exceed one second for first order, three for second, and five for third order. (See C. S. 247, page xvii.)

Abstract of Directions. An Abstract of Directions will be kept as a part of the observing procedure for each station, and will list the direction for each position, the sum and the mean directions. (C.S. 247, pages 26, 149 to 150.)

List of Directions. The List of Directions will generally list only the mean directions from the occupied station to each of the other stations. Where an eccentric instrument or signal is involved the reduction and corrected direction to the true station will be shown. (C.S. 247, page 152 to 157.)

Triangle Computations. The form for triangle computations is set up to record the computation of two full triangles of a quadrilateral on one sheet. The newly used station is always numbered last, the other stations 1 and 2 in a clockwise order, with the line 1-2 being the known line. The procedure in computing the triangles is explained in C.S. 247, pages 155 to 156.

Spherical Excess. The spherical excess in a figure is not considered in computing a plane triangle, but the spherical angle will be required in computing the geographic position. The spherical angle is larger than its plane angle, and the correction should be computed as explained in C.S. 247, pages 149, 157 and 171.

Side Checks. In the computation of a quadrilateral there are always three lines which have two values in lieu of their length. One of the requirements of triangulation is that the difference between the two values for the logarithm of the length of a line be no greater than two units in the last place. A difference for one second of the smallest distance table involved in the computation of either value for first order triangulation, can be used for second order.

These side checks are the first indication of the quality of the observed angles, as it is possible for the triangles of a quadrilateral to close within the prescribed limits and not meet the requirements of the side check. The side check condition should be satisfied before the closing of a quadrilateral is considered complete, as re-observing may be necessary.

Side equation tests should be made when the stations are tapped by order to isolate the directions that be faulty. (See C.S. 247, pages 10, 159 to 171, and xvii.)

Geographic Positions. The geographic positions of the stations should be computed by the Jamalin or Sinnott program on an IBM card or the computer of the

previous computations. A description of the [illegible] is given in S.P. 8, Formulas and Tables for Computation of Geodetic Positions. The latitude functions listed therein are necessary in computing the positions. (See also S.P. 247, pages 175 to 179.)

Triangulation Adjustment. The procedure outlined to this point is normally considered as included in the observing and field (or jobsite) computing. Due to the limited extent of the schemes surveyed by this organization, it is generally considered that when the side conditions have been satisfied further adjustment is not practical. On surveys where a coordinate system will be established and it is desirable that the values of a station remain exactly the same, independent of the direction of computation through the net, an additional adjustment is applied.

This refinement results in slight changes in the values, and a full least square adjustment is not considered practical for a limited scheme. A modified adjustment which meets the requirements of small schemes is included in this set of instructions.

COORDINATE REDUCTION OF THE THREE POINT PROBLEM

The following reduction of the three point problem is due to Mr. W. O. Pyrd, formerly Chief of the Computing Section, Division of Surveys, of the Tennessee Valley Authority, Chattanooga, Tennessee.

In the figure are shown the three points whose coordinates, indicated by the subscripts, and the point whose plane coordinates X, Y, are to be determined. The first step is to shift the origin of coordinates to the point X_3, Y_3, obtaining:

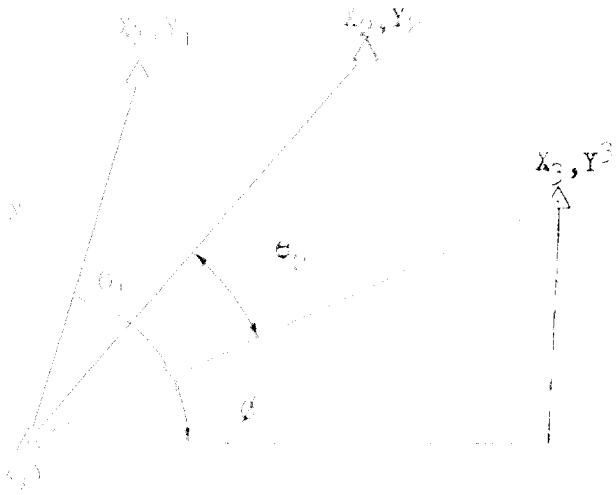
$$X_3' = Y_3' = 0$$

$$X_1' = X_1 - X_3$$

$$Y_1' = Y_1 - Y_3$$

$$X_2' = X_2 - X_3$$

$$Y_2' = Y_2 - Y_3$$



From the figure, $\tan \alpha_1 = \frac{Y_1'}{X_1'}$, and by trigonometry

$$\tan (\alpha_1 + \theta_1) = \frac{\tan \alpha_1 + \tan \theta_1}{1 - \tan \alpha_1 \tan \theta_1}$$

$$\tan (\alpha_2 + \theta_2) = \frac{\tan \alpha_2 + \tan \theta_2}{1 - \tan \alpha_2 \tan \theta_2}$$

$$\frac{Y_1' - Y'}{X_1' - X'} = \frac{\frac{Y_1'}{X_1'} + m_1}{1 - \frac{Y_1'}{X_1'} m_1} = \frac{Y_1' + m_1 X_1'}{X_1' - m_1 Y_1'}$$

$$\frac{Y_2' - Y'}{X_2' - X'} = \frac{\frac{Y_2'}{X_2'} + m_2}{1 - \frac{Y_2'}{X_2'} m_2} = \frac{Y_2' + m_2 X_2'}{X_2' - m_2 Y_2'}$$

where $\tan \theta_1 = m_1$ and $\tan \theta_2 = m_2$.

Clearing of fractions:

$$(Y_1' - Y')(X_1' - m_1 Y_1') = (X_1' - X')(Y_1' + m_1 X_1')$$

$$(Y_2' - Y')(X_2' - m_2 Y_2') = (X_2' - X')(Y_2' + m_2 X_2')$$

Performing the indicated multiplications:

$$Y_1' X_1' - m_1 Y_1'^2 - Y' X_1' + m_1 Y' Y_1' = X_1' Y_1' + m_1 X_1'^2 - X' Y_1' - m_1 X' X_1'$$

Collecting terms and dividing the first equation by m_1, the second by m_2

$(Y'^2 + X'^2) - X'(Y_1 \ldots A_1) + Y'(Y_1 + \ldots) = 0$ .... (1)

$(Y'^2 + X'^2) + X'(Y_2 \ldots A_2) - Y'(Y_2 + A_2) = 0$

Setting the second factor of the second and third terms in the above equations equal to A, B, C and D, we have

$A = Y'_1 \cot \theta_1 - X'_1$; $B = Y'_1 \cot \theta_1$ [illegible]; $C = Y'_2 \cot \theta_2 - X'_2$; $D = Y'_2 + X'_2 \cot \theta_2$

Subtracting the second of the equations (1) from the first,

$X'(A - C) - Y'(B - D) = 0$

$Y' = X' \frac{C - A}{D - B} = X'R$ where $R = \frac{C - A}{D - B}$

Substituting this value of Y' into the first of the equations (1) we have

$X'^2(R^2 + 1) + X'A - X'RB = 0$ whence

$X' = \frac{RB - A}{1 + R^2}$

And finally [illegible]

The quantity R furnishes a measure of the [illegible] of the solution, the problem becoming indeterminate as R approaches [illegible] 0/0. For example, if X'_1, Y'_1, X'_2, Y'_2 are of the order of several thousand feet, and C - A and D - B are of the order of 50 or 100 feet, the point X is close to the circle passing through the known points, and the solution is weak.

The only formal [illegible] involved in this solution is taking two cotangents from a table of natural functions. For [illegible] of the angles, these functions might become very large, [illegible]. This difficulty can be avoided by so selecting the initial line as to keep these functions down to a reasonable figure generally less than [illegible].

R might in some cases [illegible] very close to [illegible] or become practically infinite, should the point X, [illegible]. However these difficulties seldom arise in practice. In several hundred three point solutions the writer has had to reject perhaps half a dozen [illegible], and has never had to shift the initial line to get a finite value for R.

When a large number of three point determinations are to be made, it is well to solve them on a mimeographed form [illegible] the following problem is solved has been found highly satisfactory. The first step is to enter the coordinates of the known points in the appropriate places in the [illegible] part of the form. After the unknown coordinates have been found the coordinates [illegible] are entered, and the solutions checked by inversing between [illegible] and each of the known points. The difference in the azimuths of these [illegible] should check the observed angles. Space is provided for the fourth point which should be observed whenever possible, both as a check on the fix as well as the method, and for [illegible] in the event that the solution based on the selected three points should prove to be weak.

The solution differs from the derivation [illegible] first for Y instead of X. The solution can be [illegible] by omitting those lines not marked (#) by carrying the work in the computing machine.

Since the measured angles are spherical angles, each triangle will contain more than 180°, the amount by which [illegible] is termed the spherical excess and about one second for each [illegible] of area of triangle. More exactly, the total spherical excess [illegible] is obtained by the formula (see Special Publication No. 6, p. 7)

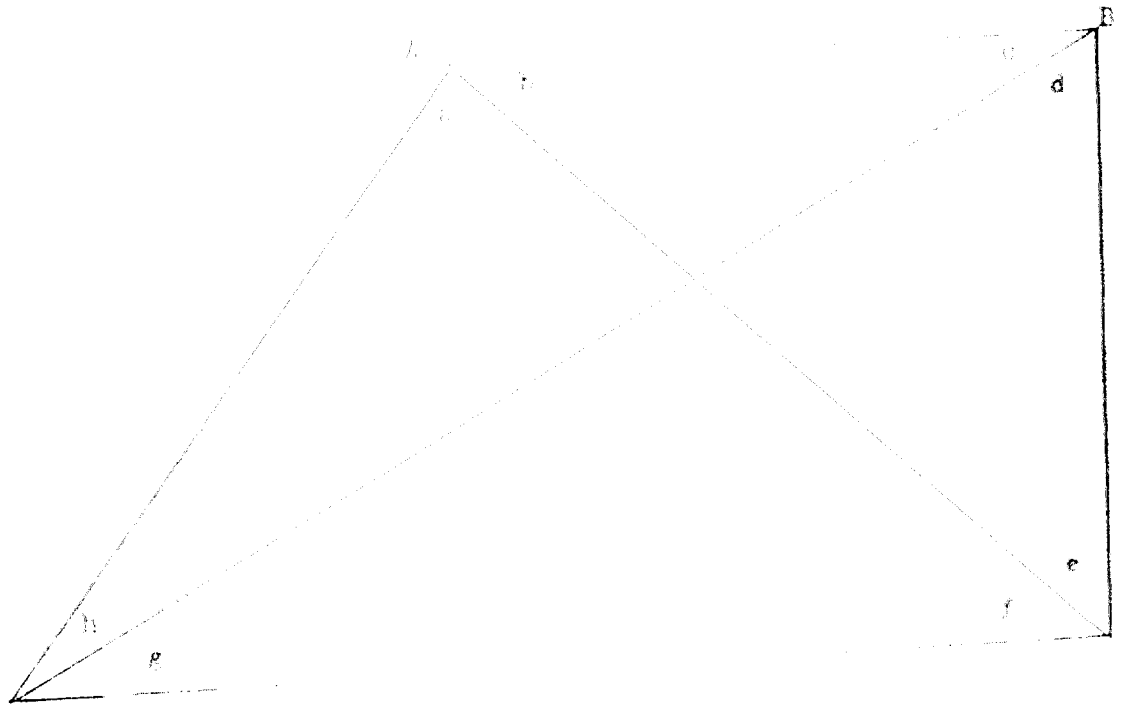
$$\epsilon = A_1 b_1 \sin(\ldots)$$

where ϵ is the spherical excess, [illegible] are the two sides and the included angle, respectively, of the corresponding [illegible]. The latter letter m is used to designate that part of the expression which depends only on the latitude and the dimensions of the spheroid and the values of log m are given with the latitude as an argument in the table on page [illegible] of Special Publication No. 6.

It is clear that no correction for spherical excess will be necessary unless the triangles are very large, and then only for the most precise work. One third of the correction is subtracted from each of the angles.

ADJUSTMENT OF A QUADRILATERAL

Before starting the adjustment of a figure or triangulation the computer should make a good clear sketch showing all the lines on which observations were made. The angles around each station of a quadrilateral are adjusted to total 360° before the figure adjustment is made. In the figure adjustment, two conditions are considered: (1) the geometric condition that the sum of the interior angles of a rectilinear figure is equal to $(n-2)180°$, in which n is the number of sides of the figure; and (2) the trigonometric condition that in any triangle the sines of the angles are proportional to the lengths of the [illegible] opposite.



1. Geometric conditions. When all the sides of a quadrilateral are measured, there are four overlapping triangles. These are shown as triangles ABC, ACD, ABD, and BCD in the figure. In each of these triangles the sum of the three angles must be 180°. Hence from the figure

$$b + c + d + e = 180^\circ \quad (1)$$
$$a + f + g + h = 180^\circ \quad (2)$$
$$a + b + c + h = 180^\circ \quad (3)$$
$$d + e + f + g = 180^\circ \quad (4)$$

Also the sum of the eight lettered angles in the figure must equal 360°, since they form the interior angles of a plane figure of four sides. This may be derived also by the addition of Eqs. (1) and (2) or (3) and (4)

$$a + b + c + d + e + f + g + h = 360^\circ \quad (5)$$

Further, since the opposite angles at the intersection of the diagonals must be equal, it follows that

$$b + c = f + g \quad (6)$$

$$d + e = a + h \quad (7)$$

Equation (6) is the equivalent of Eq. (1) minus Eq. (3) and Eq. (7) is the equivalent of Eq. (2) minus Eq. (4).

If any three of these seven equations are satisfied, the other four must of necessity be satisfied also. Equations (5), (6), and (7) are the ones most convenient to use.

The following procedure is suggested for triangulation of ordinary precision.

A. Make the station adjustment as follows: Adjust the angles around each point to make their sum equal 360° by dividing the error equally (or approximately so) among the set of angles. (Use consistently with non-repeating instrument).

B. Using the values resulting from the station adjustment A, and the eight angles a, b, c, d, e, f, g, h, as read, find their sum from 360°. Divide the difference by 8, and add algebraically and the result to each of the eight angles, thus satisfying the conditions of Eq. (5).

C. Using the adjusted values from B, find the difference between the sums (b + c) and (f + g) and divide this difference by four. Apply the result as a correction to each of the four angles, increasing each of the two whose sum is the smaller and decreasing each of the two whose sum is the larger, thus making these angles satisfy Eq. (6) without disturbing the adjustment for Eq. (5). Proceed in the same way with each of the four angles involved in Eq. (7).

2. Trigonometric Conditions. If the length of one line, as BC, is known, and the length of the side AB is to be computed, the computer may select one or another series of computation for use in accomplishing this result. For example, a solution of triangle ABC gives the length of AB, then from triangle ACE the required length of AE is found, and in the triangle ABE the length AF is found, then in AFE the length EF is computed. There are four possible chains

of route through the figure. Since results are to be given to the angle, as so far adjusted, are sufficient to make the value of the length of a computed side independent of the route used. Assume that the length of BC is known and the length of AD is to be found.

$$\text{(8)}$$

$$\text{(9)}$$

Similarly,

$$\text{(10)}$$

Equating these two values of AD,

$$\text{(11)}$$

or

$$\text{(12)}$$

Expressed in logarithmic form, this is

$$\log \sin a + \log \sin c + \log \sin e + \log \sin g$$
$$= \log \sin b + \log \sin d + \log \sin f + \log \sin h \quad \text{(13)}$$

The angles can be tested for consistency by adding their logarithmic sines in the two groups as specified and by finding the difference between the two sums.

Various adjustments by which this difference may be reduced to zero are possible. The least squares adjustment gives the most probable values for the adjusted angles, but it is somewhat more complicated than is necessary for most surveys. A simple approximate method which gives a good correction to each angle and does not disturb the geometric conditions to be followed (see adjustment of the following example) is:

(a) Record the log sines to check for the 8 angles.

(b) For each angle, record the tabular log sine and difference for 1" and write each together.

(c) Find the average logarithmic change (d) in log sine by dividing the difference between the sums by 8.

(d) Find the correction (c) for each angle.

(e) The method of applying the number of seconds of correction to each angle

(c) Add this correction to each of the observed directions (sum of values in column 2 of the angle, and subtract it from each of the angles the sum of those for sides in the figure, and that the corrected values are obtained.

If one or more of the angles is greater than 90°, adjustment D is made as just described, with the exception that the correction is subtracted. However, since the sine of an obtuse angle decreases as the angle increases, the corresponding log sines will be changed in the direction opposite to that desired. Usually the error introduced by this condition will be negligible for this approximate adjustment; if not, adjustment B should be used.

Example: Given the angles as measured in the quadrilateral (see figure), for which the station adjustment (each angle 1) has been made (see second column of following table), find the adjusted angles for both the geometric and the trigonometric conditions.

Angle	Station adjustment	Figure adjustment		
		Geometric condition		Trigonometric condition
	Adjustment A	Adjustment B	Adjustment C	Adjustment D
a	94-05-50.5	50.7	51.5	52.8
b	48-03-35.4	35.6	36.4	37.3
c	20-47-18.0	18.2	19.0	19.2
d	67-40-51.2	51.4	52.2	52.7
e	50-29-49.0	49.2	50.0	50.7
f	43-44-01.4	01.6	02.4	01.8
g	79-26-12.9	13.1	13.9	13.7
h	17-03-44.2	44.4	45.2	43.7
Sum	360-00-57.5	360-00-00.0	360-00-00.0	360-00-00.0

Adjustment D: The sum of the angles is 1.5" too large, resulting from the station adjustment A. It must be diminished by the amount of 1.5". This amount divided by the number of angles gives the amount to be subtracted (0.2") from each angle as shown in the last column in the table.

Adjustment 2 [illegible]

Dividing this difference by h_2 the correction to each angle is found to be [illegible], to be subtracted from the angles b and e, and added to the angles f and h. In like manner, the correction for each of the angles a, c, d, and g is found to be 0.2", and is added to angles a and c, and subtracted from d and g. Since these computations are carried out only to the tenths of seconds, 0.5" is added to d, 0.5" added to g, 0.2" added to a and c, and 0.2" subtracted from h_2. The resulting values are shown in the fourth column of the table.

Adjustment 3. Trigonometric Conditions. The logarithmic sines of the angles as given by adjustment 2 and as indicated in equation (32) are recorded as shown in the following tabulation, and the tabular difference for 1" is recorded for each angle.

		Difference for 1"
log sin a	9.9298876	3.0
log sin c	9.5599035	16.5
log sin d	9.8872853	12.4
log sin g	9.6424960	10.5
	9.0295724	
log sin b	9.9210202	12.9
log sin e	9.5860474	21.3
log sin f	9.8550419	26.2
log sin h	9.6414474	19.7
	9.0035569	
	9.0295724	
	0.0260155	107.4
	3.778	29.7 = $\frac{1}{s}$
	7.8 = c	

The difference between the two sums is 0.2 units of the seven places of logarithms used. This value, divided by h_2 gives the average required change in log sins, 7.8 = c. The average tabular difference for 1" is 29.7 = $\frac{1}{s}$.

Hence $\frac{c}{s} = \frac{7.8}{29.7}$ = .3" (nearly), which is the average correction to be applied to each angle. Incidentally, .3 will be added to angles a, c, d, and g, and subtracted from angles b, e, f, and h.

Since this adjustment is applied with opposite signs to alternate angles it does not disturb the geometric condition. The final adjustment is given in the fifth column of the foregoing table.

If the triangulation system consists of a chain of quadrilaterals, each quadrilateral is adjusted in the manner just described. The computations for length of the various lines are then carried through the chain from the base line

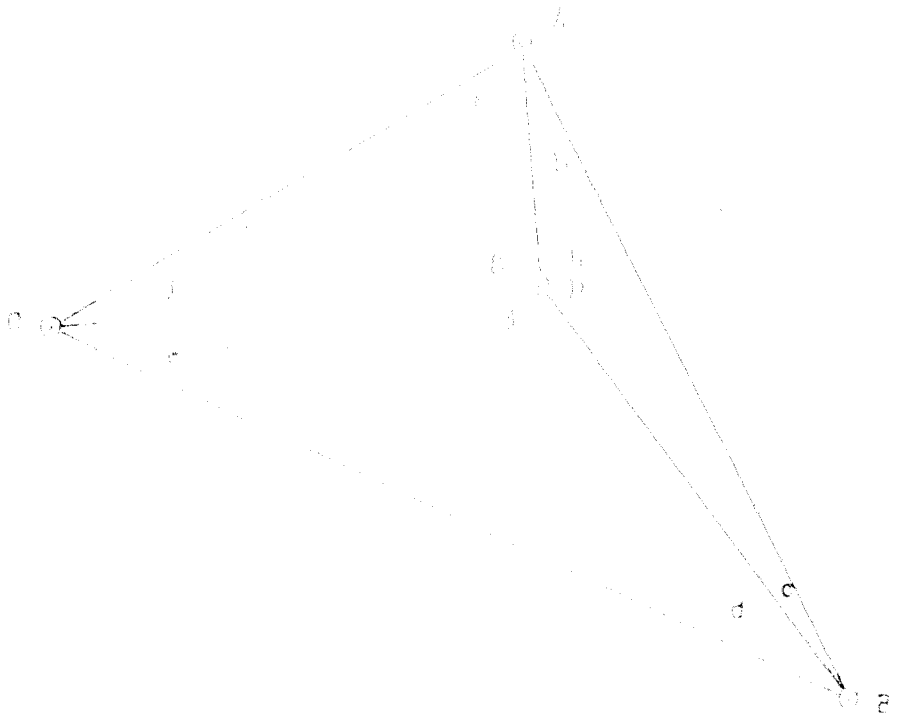
1-3					9402.64	3.9732500
1-2					7773.53	3.8906178

As in the case of the quadrilateral, the angles around each station of a central point figure are adjusted to total 360° before the figure adjustment is made. In the figure adjustments of the quadrilateral, two conditions are considered: (1) the geometric condition, and (2) the trigonometric condition.



1. Geometric Condition. At each station of a central point figure the sum of the three angles must be 180°. Hence, for the figure,

a + b + c = 180° (1)
e + c + b = 180° (2)
d + e + f = 180° (3)

Also the sum of the (in this case) eight angles forming the closed figure must total (n-2)180° where n is the number of sides of the figure (in this case 1800°)

a + b + c + d + e + f = 1080° (4)

Also the sum of the angles around the central point must total 360°.

c + b + e = 360° (5)

The following procedure is suggested for the computation of ordinary precision:

A. Make the station adjustment as follows: Adjust the angles around each point to make their sum equal 360° by distributing the error equally (or approximately so) to the several angles.

B. Using the values resulting from the station adjustment A, add the three angles of each triangle and subtract the sum from 180°, distribute the difference among the three angles (one to each angle) so that the sum will be 180°, keeping in mind that the sum of the angles around the central point must remain 360°. This will necessitate computing the angle at the central point by an unequal amount from those forming the outer figure. This satisfies Eqs. (1), (2), (3) and (5). Eq. (4) is satisfied below.

2. Trigonometric condition. There are two possible chains of route through the figure. It is necessary to see whether the angles, as so far adjusted, are so related as to make the value of a length of a computed side independent of the route used. A derivation, similar to that in the quadrilateral adjustment, gives the following equation:

$$\frac{\sin \quad \sin \quad \sin}{\sin \quad \sin \quad \sin} = 1 \qquad (6)$$

The angles are tested for satisfaction of this equation by either the logarithmic sines, as in the procedure for adjustment of a quadrilateral. The approximate method of successive trials (equally varying the angles) suggested for the quadrilateral may be used for the central point figure.

Example: Given the angles as measured in the central point figure (see fig.) for which the station adjustment (adjustment A) has been made (see second column of following table), find the adjusted angles for both the geometric and the trigonometric conditions.

Angle	Station Adjustment	Figure Adjustment	
		Geometric Condition	Trigonometric Condition
	Adjustment A	Adjustment B	Adjustment C
a	61° - 06' - 52.07	61° - 06' - 52.07	61° - 06' - 52.07
b	21° - 00' - 45.29	21° - 00' - 45.29	21° - 00' - 45.29
c	97° - 53' - 21.56	97° - 53' - 21.64	97° - 53' - 14.83
d	29° - 59' - 56.36	29° - 59' - 56.44	29° - 59' - 04.29
e	30° - 00' - 30.00	30° - 00' - 30.07	30° - 00' - 30.48
f	25° - 59' - 54.72	25° - 59' - 54.85	25° - 59' - 53.12
Sum	180° - 00' - 00.00	180° - 00' - 00.00	180° - 00' - 00.00
g	83° - 27' - 37.65	83° - 27' - 37.72	
h	148° - 45' - 04.09	148° - 45' - 04.17	
i	128° - 47' - 18.49	128° - 47' - 18.61	
Sum	360° - 00' - 00.00	360° - 00' - 00.00	

Adjustment B. Geometric Condition. The sum of the angles in each of the three triangles are:

$$\text{(1)} \quad a + b + c = 180° - 00' - 00.43''$$
$$\text{(2)} \quad d + e + g = 180° - 00' - 00.32''$$
$$\text{(3)} \quad f + h + i = 180° - 00' - 00.39''$$

In triangle (1) the sum of a + b + c is greater than 180° by +0.43". If an equal correction were applied to each angle, the correction would be -0.14". Similarly, in triangles (2) and (3), the equal corrections would be -0.11" and -0.13". Applying these equal corrections to angles a, b and c, they can be found to differ from 360° by 0.00". In the same way the correction to angle d in and i is 0.10" and from this the correction to angle c is 0.05". Condition (2) is satisfied. The remaining discrepancy in each triangle is then distributed equally between the other two angles of each triangle, thus satisfying eqs. (1), (2) and (3).

Adjustment [illegible] logarithmic [illegible] the logarithmic sines of the angles as given by [illegible] indicated by [illegible] were recorded as shown in the following tabulation, [illegible] the tabular [illegible] for each angle.

[illegible]

Log sin [illegible]	[illegible]	[illegible]
Log sin [illegible]	[illegible]	[illegible]
Log sin [illegible]	[illegible]	[illegible]
	[illegible]	

Log sin [illegible]	[illegible]	[illegible]
Log sin [illegible]	[illegible]	[illegible]
Log sin [illegible]	[illegible]	[illegible]
	[illegible]	[illegible]
	[illegible]	
	[illegible]	

The difference between the two sums is [illegible] units of the seven places of logarithms used. This value, divided by 6, gives the average required change in log sine, [illegible]. The average tabular difference for 1" is 52.0 = β. Hence

$$\frac{\alpha}{\beta} = \frac{9.0}{52.0} =$$ [illegible] (nearly), which is the average correction to be applied to each angle. Obviously, it will be added to angles [illegible], and subtracted from angles a, [illegible], e.

Since this adjustment is applied [illegible] which are alternate angles, it does not disturb the geometric conditions. The final adjustment is given in the fourth column of the foregoing table.

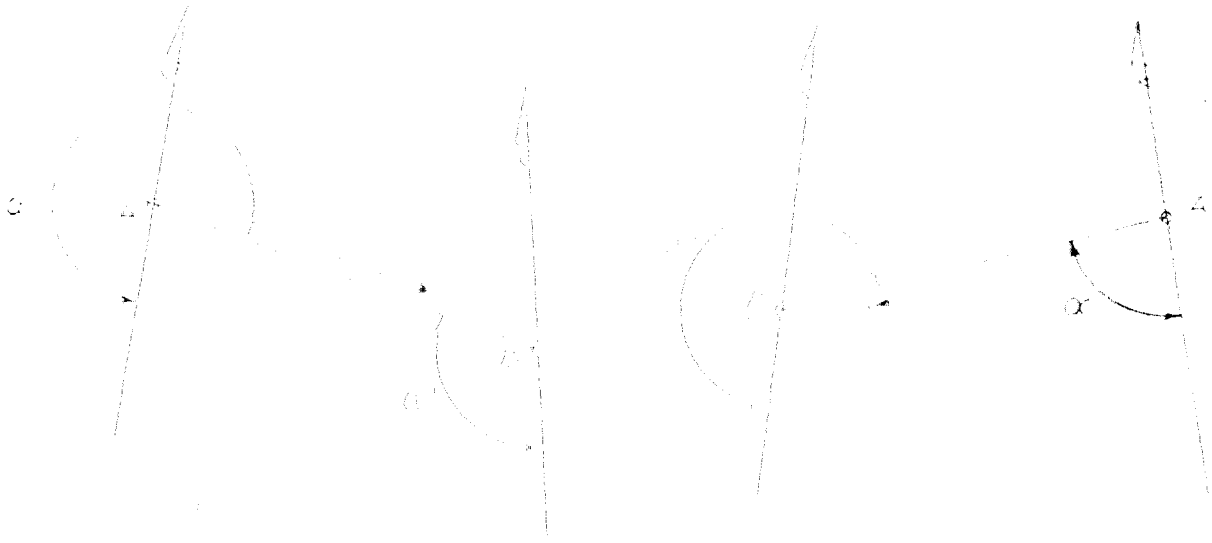


Fig. 1 — To find Latitude

Fig. 2 — To find Azimuth

Note: All west longitudes are given positive in tables.

To find Latitude: Use nearest star of magnitude 2.5 or brighter, the longitude is approximate, observe z_1 by theodolite in plane.

By inspection (Q.1 table) is Sun's or Star's (S) meridian altitude plus correction is applied to the observed altitude (O) to obtain the local altitude (Q.A). (Δλ) and (Δλ') are applied to Q.A.

To find Azimuth: Use correction of nearest star to z_1, the longitude is approximate, therefore (Δλ) is also approximate.

By inspection (Q.) or Sun's Hour Angle (t. Ang.) therefore a minor correction is applied to the observed azimuth (O) to obtain the local azimuth (Q.A). (Δλ) and (Δλ') are applied to this.

Note: In west longitudes the difference in longitude (Δλ) is subtracted, in minutes (Δλ') is applied as in Fig. 1.

To find Latitude — Fig. 3 — To find Azimuth

Note: All west longitudes are given positive.

To find Latitude: Use nearest star of magnitude 2.5 or brighter, the longitude is approximate, observe z_1 by theodolite in plane.

By inspection (Q.1 table) is Sun's or Star's (S) meridian altitude plus correction is applied to the observed altitude (O) to obtain the local altitude (Q.A). (Δλ) and (Δλ') are applied to Q.A.

PROBLEM IN EAST LONGITUDE

23 MARCH 1956

CONDITION OF TRIANGLES

Computation of the four triangles of an observed quadrangle is a required part of the field work to insure that it may be considered that the observed angles are within tolerances set up by the instructions. This is the first check on the accuracy of the observations to see that errors are within prescribed limits and that the requirements of the adjustment will be met.

In the quadrangle shown by the sketch the line MAX-CHARLIE is the base or known line. The expansion of the net is from the line AMIS-BOB as determined from this quadrangle. Two of the computations for the quadrangle are shown on the form which serves as the computation or permanent record.

The b_1 or strongest pair of triangles for use from the line AMIS-BOB are determined are entered first on the form for stations A and B, followed by the second best pair in sections C and D.

The individual triangles are always numbered in a clockwise direction with (1) at the new station and (2) and (3) at the stations on the known line. The line 2-3 is always the known line.

Computations are completed to the following order with figures rounded off to the closest hundredth for first order and to the closest tenth for second order triangulation.

(a) Enter the names of the stations and the observed angles in columns 1 and 2 corresponding with the number in pocket 1 of the individual triangles.

(b) The closing error of each triangle is distributed equally, or nearly so, between the three angles and entered in correction column 3 for angles which are determined by this operation. The correct sum of angles total 180°. It should be noted that this distribution of the closing error of the individual triangles does not satisfy the side equations of a quadrilateral adjustment but is of the first order of magnitude of a distribution differing from the correct application which cannot be satisfactory for the closure and final balancing of the angles are readjusted by the side equation adjustment or by more precise determination by the method of least squares.

(d) To complete the first triangle (A), enter logarithm 7, enter the logarithm of the known side Bc, the cologarithm of the log sin of 1 and the log sines of 2 and 3 (line 5 to the nearest logarithm 5-8, 1 and 2. Line 1- is the sum of the logarithms 5-8, 1 and 2, from the logarithm of 1-2 and 1-2 determine the triangle misclosure and enter it between (Complete the computation of triangles (B),(C) and (D) in the same manner.

(e) The spherical excess is computed from the formula $e = a, b, c, \times R$ where a, b, and c are the new sides and sin of the corresponding triangle. Three decimal places are sufficient in computing this quantity.

Obtain log e corresponding to the mean latitude of the quadrangle from S.P.no.8 page 10. To the log e add the log sin(s) of the angles 1-2, 2 and 1-3 taken from column 7. The sum is the logarithm of the spherical excess which is to be entered in column 8 on the following line and is usually nearly so, between the three angle. The correction to these per is added to the plane angles and entered in column 9.

Example — Triangle B

log e	1.402
log sin 1-2	9.999
" 2	9.999
log sin 1-3	4.182
log e	0.377 = 0.2"

The excess of 0.2" is distributed 0.1" each to one of the angles.

(e) The total correction to the observed angle is the difference between it and the spherical angle (column 6) the correction is plus or minus depending on whether the spherical angle is greater or smaller than the observed angle.

SIDE CHECKS. In the computation of a non-fixed quadrangle there are always three sides which have two determinations of their length, one of the requirements of first order triangulation is that the difference between the two values for the logarithm of the length of a side be no greater than two times the log sine difference for one second of the smallest distance angle involved in the computation of either value. Enter this value in the allowance for second side difference.

Referring to the following completed side check computation form:

Line A, 1-3	4.8000000	Diff. for 1" in 8th dec.	23
" B, 1-3	4.8000000		4
Actual diff.	00	Allowance for 2"	778
Line B, 1-3	4.8112200	Diff. for 1" in 8th dec.	41
" C, 1-3	4.8112200		4
Actual diff.	00	Allowance for 2"	164
Line B, 1-3	4.8112200	Diff. for 1" in 8th dec.	41
" D, 1-3	4.8112200		4
Actual diff.	00	Allowance for 2"	820

If this computation does not satisfy the conditions of the side check reobserving of one or more sections will be necessary. The most probable angles to reobserve may generally be determined by inspection of the computation or by applying a little care on first check. When conditions have been satisfied the quadrangle can be considered adjusted and the requirements as to further field work for triangulation of this type

ENGINEERS - CONSTRUCTORS

SURVEY DEPARTMENT

DESCRIPTION & RECOVERY

of

TRIANGULATION STATIONS

[illegible]

For establishment of a new station, at least two and preferably three reference marks should be established. The marks should be 3/8" dia. brass, or other non-ferrous metal marker, scored across [illegible]. The station mark should be stamped with the name of the station, U.S.B.M. and the year it is established. The reference point should be a punch mark as near the center of the marker as possible. This mark should be [illegible] to describe in such a way that it cannot be easily disturbed. Ideally a drilled hole would permit this; however, the ideal monument would be a 1" x 3" concrete pillar set to the depth of the frost line underlying the island soil. The reference mark should be a non-ferrous metal with a surface large enough to stamp the following on it: U.S.B.M. (3 or 4 lines) - the station name, U.S.B.M. and the date it is established. A 1" corrosion resistant brass marker is most desirable, but a large round or hexagon head brass screw or pipe cap is also acceptable. This marker should be set in a concrete post at least 3 feet in the blue mud for the station mark, or possibly less for hard rock. It should extend above and back in either a concrete slab or the rock be used, a small area 6 or [illegible] a brass escutcheon pin) should be used and the head of the pin should be large enough to stamp the required data on it.

When the station and the reference marks have been established, a complete description should be prepared containing the following items:

(1) A photo description of the station area and the RM's including what type of marker was used, how it is marked, and how it is set (concrete, grouted into a ridge, rock, etc.).

(2) A sketch of the station location to be added to publish to hide line, trees, and outstanding features or structures.

(3) A measurement of the angle at the station point to each of the reference marks from an existing station, or another station (preferably the control point station (Corral or Redoubt Rock), bay at PD) or a prominent landmark whose coordinate location is known.

(4) The measured distance from the station mark to each of the Reference Marks and the azimuth between the reference marks.

(5) The elevations of the station mark and reference marks. If no elevations are available to classify the stations, an estimate should be obtained from field observations and noted for that purpose. If no data should be entered else must be used.

(6) A brief description of the station, the equipment and methods used in making the measurements as prescribed in (3) and (4).

Where at all possible the station mark should be connected with a triangulation or wooden barrierade and the reference marks placed 2 to 4 feet on the right away from the station mark.

RECOVERY OF AN EXISTING STATION

The purpose of station recovery is to ascertain accurately the availability of an existing triangulation station using the latest and verified location already available without additional field work and to provide a check on any possible future loss or change in the station characteristics to enable it to be used without further field work.

All previous recovery notes and station descriptions should be made available to the person making the recovery to insure a full and complete recovery of the station.

When the station has been found with the help of data corresponding to that required in the preceding section, the following procedure should be obtained. This data should be obtained by as near the same means and using as near the same methods and equipment as were used in the latest station description or survey. These values should be recorded on a Permanent Mark Identification Station form which is very similar to the description of triangulation Station form. Any differences in measured values from previous values should be checked and, if found to be actual changes, should be noted. If any changes in the features of the location which might be used for referencing the station should be noted in

the recovery note and a sketch of the location by content to the sketch required for the Public Information Report [illegible] be added to the description. "

In the event a station or reference mark has been disturbed or damaged in any way, no attempt to correct that should be made on the initial recovery mission. Instructions for correcting changes, discrepancies etc. will be issued by the survey office after evaluation of the initial recovery notes from the field. When instructions or changes, deletions, etc. are issued, they will be issued in conformity with U. S. C. & G. S. procedures as outlined in U. S. C. & G. S. Spec. modified to fit details as [illegible]

FIELD NOTES

Survey Department

1. A record must be made of all field survey work in a duplicating Field Book. There are no exceptions. In some parties, such as, plane table work, in which the actual work performed is not entered in the Field Book, a Field Book entry must be prepared as mentioned in Paragraphs 9 and 11. The data not recorded in a Field Book must show the same information as the Field Book entry.

2. Two Field Books will be carried by each party Chief. One book will be used for all Domestic (non-scientific) work, the other for Scientific work.

3. In Scientific work, Stations are referred to by number (i.e. not as shot tower, detector, etc.).

4. In Domestic work, all Buildings are referred to by number (i.e. not as mess-hall, water tower, etc.).

5. In both Domestic and Scientific work it is extremely important to show elevations of structures. Unless specifically directed otherwise, this should be in relation to the site datum. The notes must include all the details of the work.

6. Angles turned must show actual details, such as, initial, double or six, and mean. Generally, no pre-planned angles will be shown. Should it be desirable to show pre-planned angles, they should be clearly labeled as such.

7. Distances measured must show actual details, such as, forward and back measurements, equipment, marks, slope, sighting, balance, etc.

8. Sketches are used to clarify the work performed. When deciding whether one is necessary, remember that the notes will be processed and used by others not as familiar with the circumstances as you may be. Label all points shown and use a north arrow.

9. The first line of the left hand page must show specific location and type of work. Examples: Building 204, Interior Layout; Station 120, W.P. location; Warehouse Area, Topography, Station 120, Levels. On the second line show the site's or its current code name, such as, Site Elmer. For work located near a site name (Elmer), such as, Elmer Reef, Sites Elmer-Fred Camp.

10. When continuous pages in the same Field Book are used, it is not necessary to repeat the listing between the initial and the first right hand page used must show "continued on page _____". On following pages, each one must show "continued from page _____" and "continued on page _____" at the bottom of the right hand page, except the bottom of the last page used shall show "End of survey". In case the pages used are not in sequence in the Field Book or are in different books, the title shall appear on each page.

11. The first line on the right half of the right hand page is used for the date and general [illegible] succeeding lines [illegible] the names of the party, state of the weather and the time of starting and stopping work.

12. An index shall be kept on the first page of each Field book, in the following manner:

PAGE	DESCRIPTION	SITE
[illegible]	Station 340, U. S. [illegible]	Ruby
[illegible]	Station 340, [illegible]	Ruby

13. Field Book originals must be turned in daily to the Survey Office.

14. ALL FIELD NOTES [illegible] THERE ARE NO EXCEPTIONS.

M. P. Curran, Jr.
16 August 1956

FIELD NOTE HANDLING

Field Note original pages (white sheets) are indexed immediately after arriving at the office. They are then thoroughly checked for accuracy and completeness. If the checker finds them unsatisfactory, he returns them to the Chief of Party with a note attached stating the details in question.

When the Field Note originals have been checked and found satisfactory, the checker turns them over to the Department Head. The latter assigns them to a computer or draftsman for necessary action, such as, preparing tabulations, drawings, etc. After all necessary action has been taken, the Field Note originals are filed in the binder labeled with the Field Book number corresponding to that of the Field Notes. At this time a note is made on the Field Note pages in red pencil stating what action was taken.

If no one is available to take the necessary action, the Department Head makes an entry in a pending file. This file is reviewed daily.

When the Chief of Party has used all of the pages in a Field Book from 2 to 30 inclusive, he turns in the Field Book Index kept on Page 1. The Field Book originals are checked and the Chief of Party called to account for any missing pages.

The Index of Field books consists of 3 x 5 inch cards kept in a standard metal file box. A Domestic and a Scientific File is kept for each Atoll. These are subdivided as follows:

DOMESTIC

SITE

Buildings	Numerical order
Roads	Alphabetical order
Sewers	Alphabetical order
Water Lines Electrical (Underground) Electrical (Overhead)	Alphabetical order of sheets of Site Plan
Topography	Separate when not directly related to any of above subdivisions
Hydrography	Separate when not directly related to any of above subdivisions
Marine Facilities	Separate when facility does not carry a building number
Horizontal Control	Chronological order
Vertical Control	Chronological order

SCIENTIFIC

Numerical

Station numbers and files only on Department cards

Files

Stations	Numerical order
Cables	Files established for each type

When the Field Note contains no more than one page of entry, a note is made on each

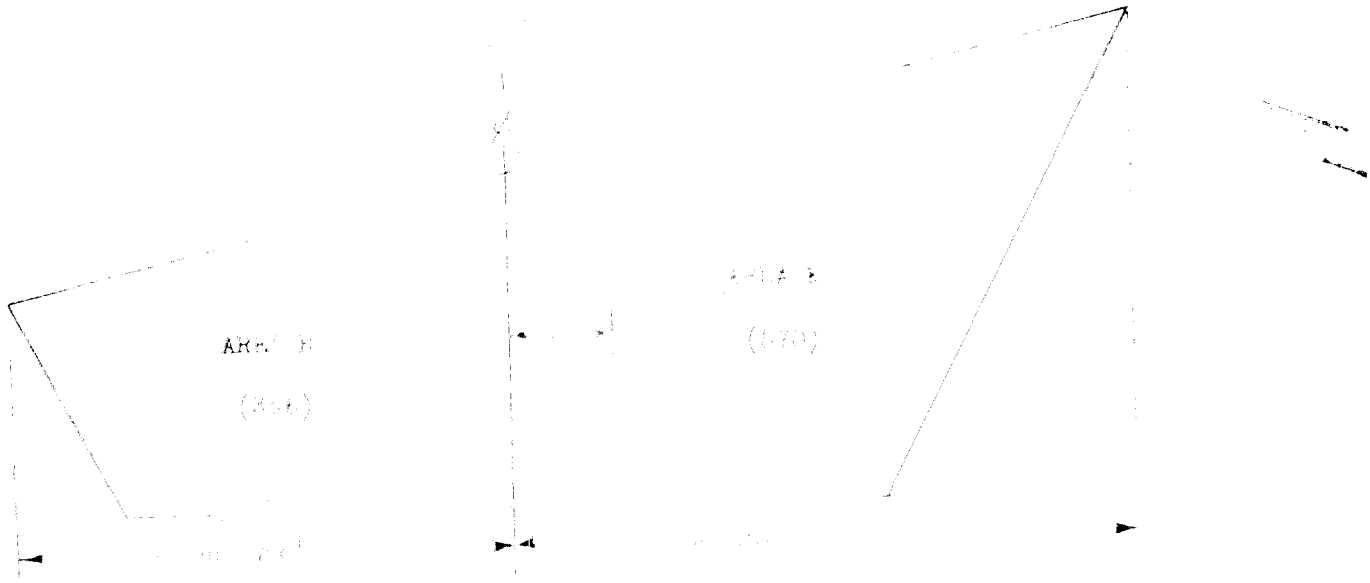
Bisect line "W" on center of gravity ( )
is 1/3 the distance from this point

Eccentricity of the section is the distance
the center of gravity to centerline.



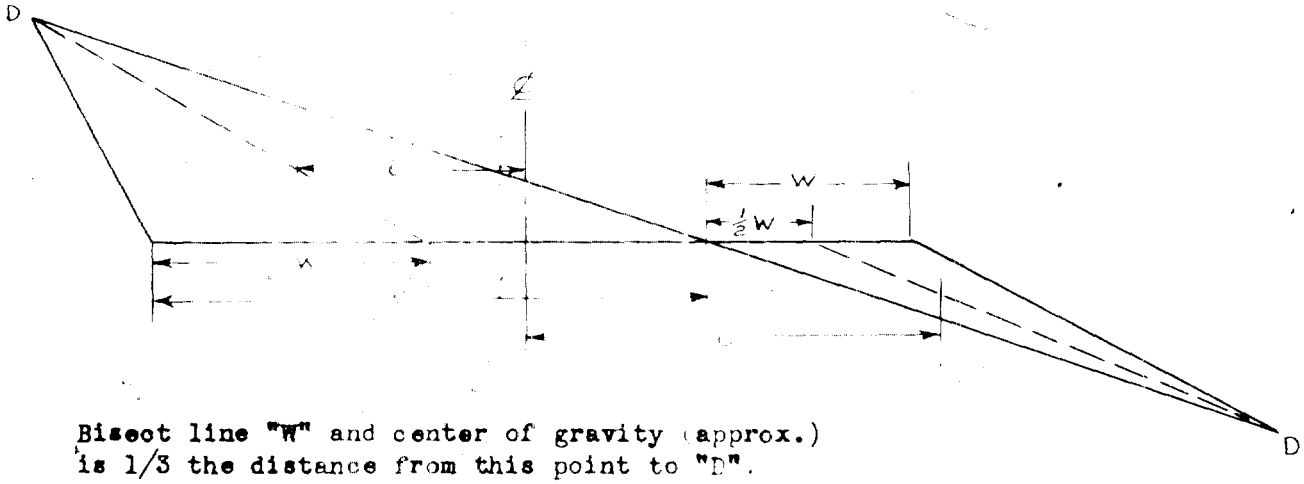
$$e = \frac{I_x \cdot S}{3I}$$ ( )

$$= \frac{S}{3448} \times 324$$

Determine area of sections each side of the centerline.
Solve the statical moment centerline (a leg of one or each
side and apply the formula.

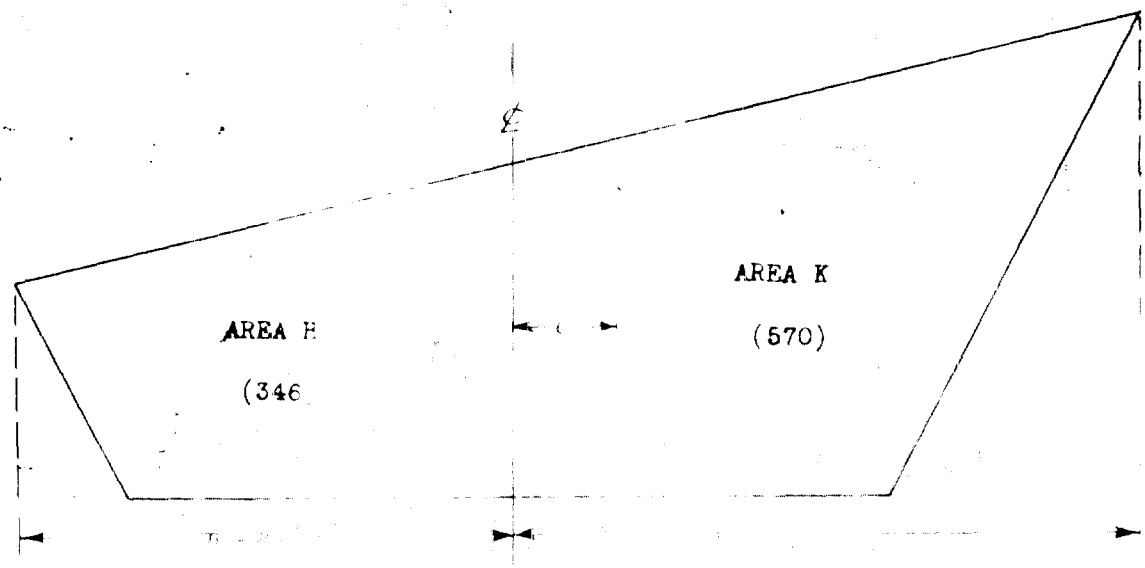
COMPENSATION FOR CURVATURE - [illegible] VARIAGE CALCULATIONS

ECCENTRICITY OF CENTER OF GRAVITY OF SECTION



Bisect line "W" and center of gravity (approx.) is 1/3 the distance from this point to "D".

Eccentricity of the section is the distance from the center of gravity to centerline.



$$e = \frac{n + m}{3A} (K - H)$$

H = 346
K = 62[illegible]
Sum [illegible] Diff. = 224

$$e = \frac{69}{2448} \times 2.4[illegible]$$

Determine area of sections each side of the centerline. Scale the distance from center line to [illegible] of cut on each side and apply the formula.

[illegible] 615 333 cu-yds. per 40 ft. = 161.723 per 0.1 ft.

Coefficient of Expansion - 0.0000004
Standard Temperature - 20° C.
Indicated corrections are decimal parts of a meter in the 5th place and are plus for temperature above 20°
