Dear Bruce:

The enclosed tables are self explanatory. The ratio's in Tables 1 and 2 are based upon data from the Northern Marshall Islands Survey (NMIS) and our continuing program at Eneu Island. I think the predicted doses in Table 3 (based on the relative concentrations in Table 2) are certainly indicative of at least the magnitude of the doses we will see for the ingestion pathway when we run the final dose codes.

The marine pathway, ground-water and cistern water pathway and the EGG report on the external gamma exposure pathway are already published. These reports (and doses) combined with the enclosed predictions for the ingestion pathway, put the total dose picture for the NMIS pretty well in perspective.

In general, the final conclusion will be that for all atolls other than Rongelap, the total predicted doses (from all pathways) will be rather low and in most cases will be in the range of natural background exposures in the United States and less than background doses in many areas of the world. The doses for Rongelap will be less than Eneu Island doses.

I do emphasize that the ingestion pathway doses are estimated at this time and that you use the data presented in Tables 1,2 and 3 in a quantitative or semi-quantitative manner at this stage. The data should not be released at this time. We will supply the final food chain doses at a later time.

Sincerely,

A handwritten signature in black ink, appearing to read "Bilby".
