

show excretion levels not too much higher than the minimum detectable by equipment. The last table, Table 4, shows that the internal whole body dose equivalent contributes 65% of the total whole body dose equivalent for 1978. The internal dose equivalent is mainly due to the ^{137}Cs body burden. The contribution of ^{90}Sr to whole body equivalent rate is negligible, being 1/60 of the bone dose equivalent rate. However, ^{90}Sr is harmful primarily as a bone seeker, thus, comparison in terms of maximum permissible bone dose equivalent rate would be more appropriate for this radionuclide.

Cua to McCraw

October 18, 1978

Sources of error are indicated and the assumptions made are expressed where needed. The results quoted are generally conservative. New information from an on-going Marshall Island control-urine sampling and a parametric study to determine the effect of non-constant, non-continuous uptake and difference in time post uptake and pre-bio-assay sampling, will establish the extent of the conservativeness of these results.

Please feel free to call me (FTS 666-2503) if you have questions on the ^{90}Sr results.

Sincerely,

Florence T. Cua

Maximum permissible whole body dose equivalent rate - 500 mRem/year

Maximum permissible bone dose equivalent rate - 3,000 mRem/year

N.D. - No Data

- (1) Initial data were taken from 1975 UCRL Report 51379 Rev. 1 living pattern #2, adult population only.
- (2) Data taken from 1974, 1977 and 1978 WEC reports c/o Robert Miltenberger. Body burdens of 1970-1974 assumed to be constant at the 1974 level due to lack of data on individuals prior to 1974.
- (3) Body burden for 137Cs in the years 1975 and 1976 were obtained from interpolation between 1974 and 1977 data.
- (4) ICRP 20 model was used. For the year 1970-1974, the (pCi/liter) values reported are mean values, however, the dose equivalent values are the conservative values, assuming 1.4 liter/day excretion for all and an uptake interval of 0.5 years for 1970, 1 year for 1971, 2 years for 1972, 3 years for 1973 and 4 years for 1974. The 1977 and 1978 dose equivalent values are the mean of the individual dose equivalent values. The residence time on the island of an individual was considered the uptake time of 90Sr for the individual.
- (5) The standard deviation (15) reported gives an idea of the variability among individuals in the population. Error in the whole body counting procedure would have a worst case value of +25%, whereas error in the urine analysis program would be typically +20% due to counting statistics and +25% due to the assumption of daily excretion of 1.4 liter for men and 1 liter for women and children when in fact they are excreting less.
